## The NASA STI Program Office . . . in Profile

Since its founding, NASA has been dedicated to the advancement of aeronautics and space science. The NASA Scientific and Technical Information (STI) Program Office plays a key part in helping NASA maintain this important role.

The NASA STI Program Office is operated by Langley Research Center, the lead center for NASA's scientific and technical information. The NASA STI Program Office provides access to the NASA STI Database, the largest collection of aeronautical and space science STI in the world. The Program Office is also NASA's institutional mechanism for disseminating the results of its research and development activities. These results are published by NASA in the NASA STI Report Series, which includes the following report types:

- **TECHNICAL PUBLICATION.** Reports of completed research or a major significant phase of research that present the results of NASA programs and include extensive data or theoretical analysis. Includes compilations of significant scientific and technical data and information deemed to be of continuing reference value. NASA counterpart of peer-reviewed formal professional papers, but having less stringent limitations on manuscript length and extent of graphic presentations.
- **TECHNICAL MEMORANDUM.** Scientific and technical findings that are preliminary or of specialized interest, e.g., quick release reports, working papers, and bibliographies that contain minimal annotation. Does not contain extensive analysis.
- **CONTRACTOR REPORT.** Scientific and technical findings by NASA-sponsored contractors and grantees.

- **CONFERENCE PUBLICATION.** Collected papers from scientific and technical conferences, symposia, seminars, or other meetings sponsored or co-sponsored by NASA.
- **SPECIAL PUBLICATION.** Scientific, technical, or historical information from NASA programs, projects, and missions, often concerned with subjects having substantial public interest.
- **TECHNICAL TRANSLATION.** English-language translations of foreign scientific and technical material pertinent to NASA's mission.

Specialized services that complement the STI Program Office's diverse offerings include creating custom thesauri, building customized databases, organizing and publishing research results ... even providing videos.

For more information about the NASA STI Program Office, see the following:

- Access the NASA STI Program Home Page at <http://www.sti.nasa.gov>
- E-mail your question via the Internet to [help@sti.nasa.gov](mailto:help@sti.nasa.gov)
- Fax your question to the NASA STI Help Desk at (301) 621-0134

## Abstract

*An investigation was conducted in the NASA Langley Transonic Dynamics Tunnel to acquire data for use in assessing the ability of current and future comprehensive analyses to predict helicopter rotating-system and fixed-system vibratory loads. The investigation was conducted with a generic model helicopter rotor system using blades with rectangular planform, no built-in twist, uniform radial distribution of mass and stiffnesses, and a NACA 0012 airfoil section. Rotor performance data, as well as mean and vibratory components of blade bending and torsion moments, fixed-system forces and moments, and pitch link loads were obtained at advance ratios up to 0.35 for various combinations of rotor shaft angle-of-attack and collective pitch. The data are presented without analysis.*

## Introduction

Vibratory loads, and the resulting vibrations, have always been a problem for helicopters. Excessive vibration levels have adverse effects on crewmembers, passengers, and aircraft components. As mission requirements force helicopters to fly faster, the vibration problem becomes more pronounced because of the increased vibratory loads caused by the higher speeds. Decreased vibration levels result in enhanced productivity and effectiveness of helicopters through reduced crew and passenger fatigue and discomfort, increased aircraft component reliability, and reduced aircraft maintenance costs.

The primary contributor to helicopter vibration is the main rotor. Vibratory loads caused by harmonic variations in main-rotor blade airloads are transmitted through the rotor shaft and into the fuselage. Accurate prediction of these vibratory loads is an important first step in reducing vibrations because it permits attacking the problem at the source and enables researchers to develop an understanding of the roles played by various design parameters with regard to helicopter vibration (refs. 1 & 2). References 3-5 indicate that the state-of-the-art of rotor loads analyses has made the successful prediction of rotor loads difficult, particularly for the higher frequency loads that are of primary interest when addressing helicopter vibrations. Furthermore, reference 6 indicates that the prediction capability

of current analyses has not improved greatly over the years. However, some success has been reported in references 7-9 where optimization methods are used in conjunction with comprehensive analyses to predict vibratory loads and design low-vibration main-rotor blades.

The next step in rotorcraft vibratory loads prediction will involve the coupling of computational fluid dynamics (CFD) methodologies with comprehensive analyses. The expected benefits of incorporating CFD in vibratory loads predictions include improved calculations of induced velocity fields and wake characteristics. Two examples of the use of CFD in rotorcraft calculations are presented in references 10 and 11 and indicate mixed results with regard to the successful use of CFD methodologies.

The search for analyses that can accurately predict rotor vibratory loads will continue until an analysis is identified that can provide a designer confidence that the goal of lower vibration can be met before committing to a costly fabrication process. To aid in the identification of such an analysis, an investigation was undertaken in the NASA Langley Transonic Dynamics Tunnel (TDT) using a generic model rotor system to acquire fixed- and rotating-system vibratory loads data. The model rotor blades used to obtain these data are elementary in both design and construction, utilizing a rectangular planform, no built-in twist, constant structural properties along

the blade, and a symmetrical airfoil section. Additionally, the blade spar is metallic and rectangular in cross-section to provide stable, flat surfaces for mounting the strain-gage bridges that measure blade bending and torsion loads. The blade characteristics should be easy to incorporate in analytical models, making the data obtained during this investigation useful as a benchmark in identifying the mechanisms that produce rotorcraft vibratory loads as well as determining the ability of current and future analyses to predict these loads.

## Symbols

The positive directions of fixed-system forces, moments, angles, and velocities and blade bending and torsion moments are shown in figure 1. The symbols in parentheses are used in the data tables.

$A$	fixed-system strain-gage balance axial force, lb	$C_D$	rotor drag coefficient, $D / \rho\pi R^2(\Omega R)^2$
$A_n$ (Mag)	magnitude of $n^{\text{th}}$ harmonic of blade, strain-gage balance, or pitch link load, in-lbs or lbs	$C_L$	rotor lift coefficient, $L / \rho\pi R^2(\Omega R)^2$
$A_0$ (MEAN)	mean value of Fourier analysis of blade, strain-gage balance, or pitch link load, in-lbs or lbs	$C_Q$	rotor torque coefficient, $Q / \rho\pi R^3(\Omega R)^2$
$A_1$	rotor first-harmonic lateral cyclic pitch angle, deg	$c$	nominal blade chord, 3.625 in
$a$	speed of sound, ft/sec	$D$	rotor drag, $\text{lb}, N \sin \alpha_S + A \cos \alpha_S$
$a_{1s}$	rotor first-harmonic longitudinal flapping angle with respect to the rotor shaft, deg	$d$	rotor diameter, 9.370 ft
$B_1$	rotor first-harmonic longitudinal cyclic pitch angle, deg	$g$	gravitational constant, 32.2 ft / sec <sup>2</sup>
$b$	number of blades	$I_\theta$	blade section torsional mass moment of inertia, slug-ft <sup>2</sup> / ft
$b_{1s}$	rotor first-harmonic lateral flapping angle with respect to the rotor shaft, deg	$L$	rotor lift, $\text{lb}, N \cos \alpha_S - A \sin \alpha_S$
		$L_{\text{Nom}}$	nominal rotor lift, lb
		$M_T$	rotor tip Mach number, $\Omega R / a$
		$N$	fixed-system strain-gage balance normal force, lb
		$n$	harmonic index
		$nP$	$n^{\text{th}}$ harmonic of rotor rotational frequency
		$PM$	fixed-system strain-gage balance pitching moment, in-lb
		$RM$	fixed-system strain-gage balance rolling moment, in-lb
		$Q$	rotor shaft torque measured by fixed-system strain-gage balance, in-lb
		$R$	rotor radius, 4.685 ft
		$r$	spanwise distance along blade radius measured from center of rotation, in

S	fixed-system strain-gage balance side force, lb
V	free-stream velocity, ft / sec
YM	fixed-system strain-gage balance yawing moment, in-lb
z	distance from wind-tunnel floor to rotor hub, ft
$\alpha_s$	rotor shaft angle of attack, deg
$\theta$	rotor blade collective pitch angle at $0.75R$ , deg
$\mu$	rotor advance ratio, $V / \Omega R$
$\rho$	test-medium mass density, slugs / $ft^3$
$\varphi_n$ (Phase)	phase angle of $n^{\text{th}}$ harmonic of blade, strain-gage balance, or pitch link load, deg
$\psi$	rotor blade azimuth angle, deg
$\Omega$	rotor rotational velocity, rad / sec
$\omega$	natural frequency of rotating blade mode, rad / sec
Subscripts:	
Nom	nominal

## Apparatus and Procedures

### Wind Tunnel

The testing was conducted in the Langley Transonic Dynamics Tunnel (TDT), schematics of which are shown in figure 2. The TDT is a continuous-flow tunnel with a slotted test section and is capable of operation up to Mach 1.2 at stagnation pressures up to one atmosphere. The tunnel test section is 16 feet square with cropped corners and has a cross-sectional area of 248 ft<sup>2</sup>. The tunnel uses either air or a heavy gas as its test

medium. The tunnel was originally constructed to use R-12 as the test medium (ref. 12). Environmental concerns raised in the late-1980s regarding the continued use of R-12 led to a NASA decision to replace R-12 with the essentially equivalent refrigerant R-134a. Conversion of the TDT heavy gas test medium to R-134a was completed in 1997 and is described in references 13 and 14. The investigation documented in this report was conducted before the conversion to R-134a and so R-12 at a nominal density of 0.006 slugs/ft<sup>3</sup> was used as the test medium. The use of a heavy gas test medium with a high density and low speed of sound, such as either R-12 or R-134a, aids the matching of model-rotor-scale Reynolds number and Mach number to full-scale values. Furthermore, some restrictions on model structural design are eased, and dynamic similarity is still maintained. The heavier test medium permits a simplified structural design to obtain the required stiffness characteristics, and thus eases design and fabrication requirements of the model (ref. 15).

### Model Description

The rotor model used in this investigation was a four-bladed, articulated rotor with coincident lead-lag and flapping hinges operating with a pitch-flap coupling ratio of 0.5 deg/deg (flap up, pitch down). The attachment point of the blade pitch link was 1.4 inches aft of the blade pitch axis and 0.7 inches inboard of the blade flapping hinge. The rotor blades were rectangular in planform and used a rectangular aluminum spar as the primary load-carrying member. Calculated model blade structural properties and rotating natural frequencies are presented in Table I. The calculated blade rotating frequencies were determined by using the second-generation version of the Comprehensive Analytical Model of Rotorcraft Aerodynamics and Dynamics (CAMRAD-II) (ref. 16) code. Measured rotating frequencies were determined during the course of the test by a rotating shake test.

The airfoil used over the entire blade length was a NACA 0012 with the airfoil contour provided by a Rohacell WF-51 foam core bonded

to the aluminum spar with the spar centered at the blade quarter chord. The foam core was wrapped with a fiberglass skin consisting of two layers of 0.004 inch thick E-glass oriented at +/- 20 degrees. Brass weights were used at the blade leading edge and 3 inches aft of the leading edge to place the blade center of gravity at the blade quarter chord and to provide the desired blade torsional inertia. The blades had no built-in twist. Blade cross-sectional details, planform geometry and construction details are shown in figure 3. One blade was instrumented with resistance-wire strain-gage bridges bonded to the blade spar at the blade quarter chord and calibrated to measure blade structural moments about three axes at several blade radial stations. Flapwise (out-of-plane) strain-gage bridges were installed at 23, 37, 51, 63, 74, and 82 percent radius. Chordwise (in-plane) strain-gage bridges were installed at 30, 45, and 77.23 percent radius, and torsional strain-gage bridges were installed at 35, 60, and 85 percent radius. The blade design parameters were chosen in order to provide a simple structure that could be easily modeled analytically, could be built for a minimal cost, and would provide a consistent data set for correlation with analysis.

The blades were tested using the Aeroelastic Rotor Experimental System (ARES) testbed shown in figures 4 and 5. The ARES has a streamlined helicopter fuselage shape enclosing the rotor controls and drive system, and is powered by a variable frequency synchronous motor rated at 47-hp output at 12,000 rpm. The motor is connected to the rotor shaft through a belt-driven two-stage speed reduction system. The ARES rotor control system and rotor shaft angle of attack are remotely controlled from the wind-tunnel control room. The rotor shaft angle of attack is varied by an electrically controlled hydraulic actuator. Blade collective pitch and lateral and longitudinal cyclic pitch are input to the rotor through the swashplate, which is positioned by three hydraulic actuators.

Instrumentation on the ARES testbed allows continuous displays of model control settings, rotor forces and moments, blade loads, and pitch link loads. For this test all four pitch links were

instrumented to provide tension and compression loads. The ARES rotor shaft pitch attitude is measured by an accelerometer, and rotor control positions are measured by linear potentiometers connected to the swashplate. Rotor blade flap and lag angles are measured by rotary potentiometers mounted on the rotor hub and geared to the blade cuff. Rotor shaft speed is determined by a magnetic sensor. The rotating blade data are transferred to the fixed system through a 30-channel slip-ring assembly. A six-component strain-gage balance mounted below the pylon and drive system measures rotor forces and moments. The balance is fixed with respect to the rotor shaft and pitches with the fuselage. The balance does not sense fuselage forces and moments.

## Test Procedure

During this test, data were acquired in both hover ( $\mu = 0.0$ ) and in forward flight ( $\mu = 0.06 - 0.35$ ). In hover, data were obtained at  $z/d = 0.85$ ,  $M_T = 0.65$  and zero degrees shaft angle of attack over a range of blade collective pitch values. At each test point in forward flight the rotor rotational speed and tunnel conditions were adjusted to give the desired values of tip Mach number and advance ratio. The testbed was then pitched to the desired shaft angle of attack. Blade collective pitch was changed to obtain variations in rotor lift. At each collective pitch setting, cyclic pitch was used to remove rotor first-harmonic flapping with respect to the shaft or to set a desired value of first-harmonic flapping with respect to the shaft depending on the desired test condition. Data were then recorded at each value of collective pitch. The maximum value of collective pitch attained at each shaft angle of attack was determined in most cases by blade load limits. Rotor aerodynamic performance and blade loads were measured at nominal advance ratios of 0.06, 0.07, 0.08, 0.09, 0.13, 0.16, 0.20, 0.25, 0.30, and 0.35 for shaft angles of attack from 0 degrees to -6 degrees. Performance and loads data were also obtained at nominal advance ratios of 0.08, 0.11, 0.13, 0.16, 0.20, 0.225, 0.25, 0.275, 0.30, and 0.325 at constant nominal rotor lift values of 160 lbs ( $C_L = 0.00366$ ), 180 lbs ( $C_L = 0.00412$ ), and 200 lbs ( $C_L = 0.00458$ ) for shaft angles of

attack representative of 1g flight at each advance ratio. At the nominal advance ratios of 0.16, 0.20, 0.225, 0.25, 0.275, 0.30, 0.325 data were also obtained at  $\pm 1$  degree of rotor first harmonic longitudinal and lateral flapping with respect to the shaft at a nominal rotor lift value of 180 lbs.

Model deadweight tares were determined throughout the range of shaft angles of attack with the blades on and with them removed. Aerodynamic rotor hub tares were determined with the blades removed throughout the ranges of shaft angles of attack and advance ratios investigated. Both deadweight and aerodynamic hub tares have been removed from the data presented. No corrections for tunnel wall effects were applied to the data.

## Measurement Quality

The quality of the performance data obtained during this investigation was addressed. During the test, 234 data points were obtained. Out of this data set, 51 points were repeated. The repeated points were obtained entirely within a particular test run. A test run is defined as data points obtained by increasing then decreasing  $\theta$  for a series of constant values of  $\alpha_s$  and  $\mu$ . Time constraints precluded obtaining any run-to-run repeat points. The average deviation in  $C_L$ ,  $C_D$ , and  $C_Q$  ( $\Delta C_L$ ,  $\Delta C_D$ ,  $\Delta C_Q$ ) was determined between the originally obtained data points and the repeat data points. The average deviations for constant values of  $M_T$ ,  $\mu$ ,  $\alpha_s$ ,  $\theta$ , and zero rotor first-harmonic flapping with respect to the shaft were determined to be as follows:

$$\Delta C_L \dots \dots \dots +0.00002 \text{ to } -0.00002$$

$$\Delta C_D \dots \dots \dots +0.00001 \text{ to } -0.00000$$

$$\Delta C_Q \dots \dots \dots +0.00000 \text{ to } -0.00000$$

The values of  $\Delta C_L$ ,  $\Delta C_D$ , and  $\Delta C_Q$  are presented to the same level of accuracy, i.e., number of decimal places, as the performance data presented in this report.

## Presentation of Results

The rotor performance and loads data obtained during this investigation are presented in both figures and tables. Rotor performance is presented as plots of  $C_L$  versus  $C_Q$  for hover, and in forward flight as plots of  $C_L$  versus  $C_D$  and  $C_L$  versus  $C_Q$  for advance ratios from 0.09 to 0.35. At advance ratios of 0.06, 0.07, and 0.08, insufficient data were obtained for meaningful plots to be created, so results at these advance ratios are only presented in tabular form. The rotor performance data obtained at constant nominal values of rotor lift and with variations from trim in rotor first-harmonic flapping angles with respect to the shaft are also only presented in tabular format. The rotor performance parameters  $C_L$ ,  $C_D$ , and  $C_Q$  are tabulated along with the corresponding rotor control angles  $A_1$ ,  $B_1$ , and  $\theta$  for all forward flight data points. In hover, no values of  $A_1$  and  $B_1$  are presented. For the conditions of constant nominal rotor lift and non-trim rotor first-harmonic flapping with respect to the shaft, the corresponding nominal rotor lift and flapping values are also tabulated. Each plotted and tabulated data point is identified by a specific test run number and point number. For example, point 150 within run 7 is indicated as 7.150 in the plots. The rotor loads data are presented in tabular form and consist of the mean (MEAN), oscillatory (1/2 peak to peak (1/2 P-P)), and first ten harmonics (1P to 10P) of a Fourier analysis of the instrumented blade strain-gage signals, fixed-system strain-gage balance signals and pitch link strain-gage signals. Pitch link loads are presented in the tables for blades 1 through 4 with blade 1 defined as the reference blade and blades 2 – 4 numbered clockwise, when viewed from above, from blade 1. The loads data, like the performance data, are identified by a specific test run number and point number, thus allowing cross-referencing of loads and performance data. No information is presented for the flapwise strain-gage bridge installed at 82 percent radius because of a failure in the bridge. Also, no results are presented in Table V (Run 9) for the torsional strain-gage bridge installed at 85 percent radius because of instrumentation problems during the run. The magnitudes (Mag) of the blade flapwise,

chordwise and torsion loads are presented in inch-pounds, the magnitude of the fixed-system strain-gage balance loads are presented in pounds and inch-pounds, and the magnitude of the pitch link loads is presented in pounds. The magnitude of all phase angles (Phase) is presented in degrees referenced in the direction of rotor rotation from zero degrees over the tail of the ARES testbed. The sign conventions for the blade loads data are as follows: flapwise up, positive; chordwise aft, positive; torsion blade nose-up, positive; and pitch link load for a tension load, positive. The sign conventions for the fixed-system strain-gage balance forces and moments and blade bending and torsion moments are presented in figure 1. The total blade load, pitch link load or strain-gage balance load at any azimuth location may be reconstructed from the tabulated harmonics by using the following equation:

$$Load = A_0 + \sum_{n=1}^{10} A_n \sin(n\psi + \phi_n)$$

The data are presented in the following order:

	Table Number	Figure Number (Performance Data Only)
Hover Performance	II	6
Performance and loads, $\mu = 0.06-0.08$	III	---
Performance and loads, $\mu = 0.09 - 0.20$	III	7 - 10
Performance and loads, $\mu = 0.25$	IV	11
Performance and loads, $\mu = 0.30$ and $0.35$	V	12-13
Performance and loads at constant rotor lift and non- trim flapping, $\mu = 0.08 - 0.325$	VI	---

## Concluding Remarks

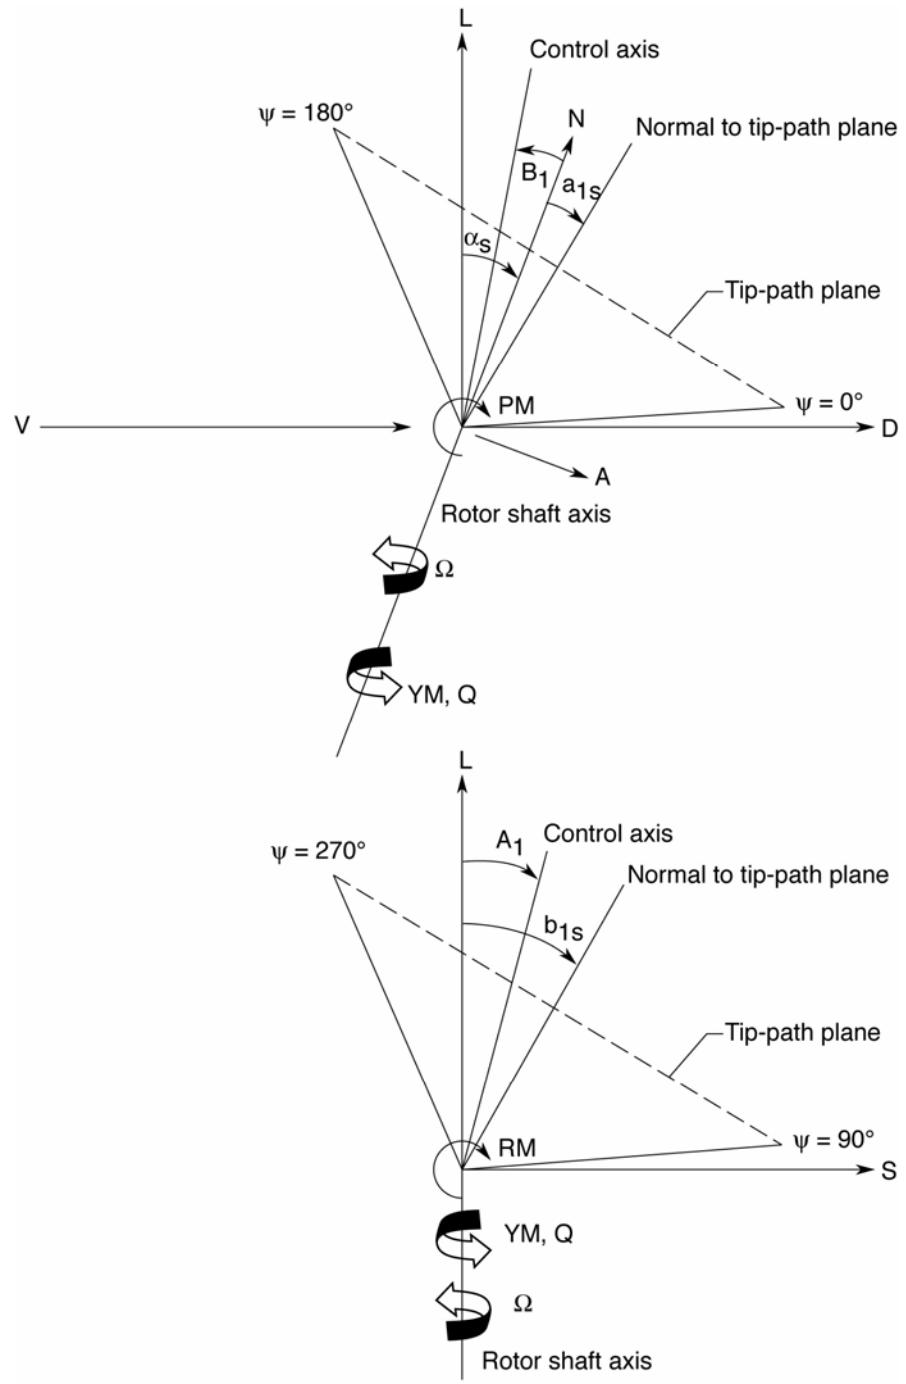

Rotor performance data, as well as mean and vibratory components of blade bending and torsion moments, fixed-system forces and moments, and pitch link loads data have been obtained with a model articulated helicopter rotor using generic rotor blades. The data were obtained at advance ratios up to 0.35 for various combinations of rotor shaft angle-of-attack and blade collective pitch. These data will be useful as a benchmark for assessing the ability of current and future comprehensive analyses to predict helicopter rotating-system and fixed-system vibratory loads.

14. ABSTRACT					
<p>An investigation was conducted in the NASA Langley Transonic Dynamics Tunnel to acquire data for use in assessing the ability of current and future comprehensive analyses to predict helicopter rotating-system and fixed-system vibratory loads. The investigation was conducted with a generic model helicopter rotor system using blades with rectangular planform, no built-in twist, uniform radial distribution of mass and stiffnesses, and a NACA 0012 airfoil section. Rotor performance data, as well as mean and vibratory components of blade bending and torsion moments, fixed-system forces and moments, and pitch link loads were obtained at advance ratios up to 0.35 for various combinations of rotor shaft angle-of-attack and collective pitch. The data are presented without analysis.</p>
